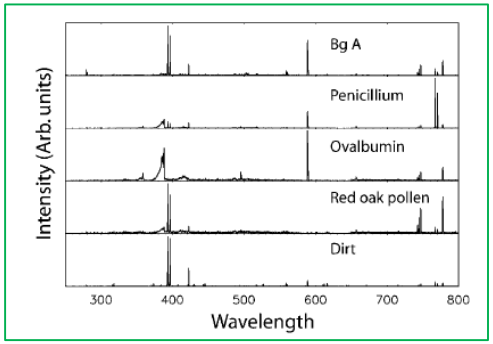
Volume 57, Number 10, 2003 APPLIED SPECTROSCOPY 1207



Bacillus subtilis var. niger

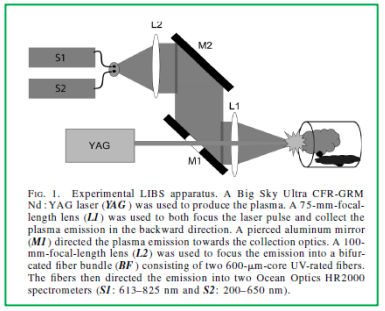


FIG. 1. Experimental LIBS apparatus. A Big Sky Ultra CFR-GRM Nd:YAG laser (*YAG*) was used to produce the plasma. A 75-mm-focal-length lens (*L1*) was used to both focus the laser pulse and collect the plasma emission in the backward direction. A pierced aluminum mirror (*M1*) directed the plasma emission towards the collection optics. A 100-mm-focal-length lens (*L2*) was used to focus the emission into a bifurcated fiber bundle (*BF*) consisting of two 600-µm-core UV-rated fibers. The fibers then directed the emission into two Ocean Optics HR2000 spectrometers (*S1*: 613–825 nm and *S2*: 200–650 nm).

Laser-induced breakdown spectroscopy of bacterial spores, molds, pollens, and protein: initial studies of discrimination potential

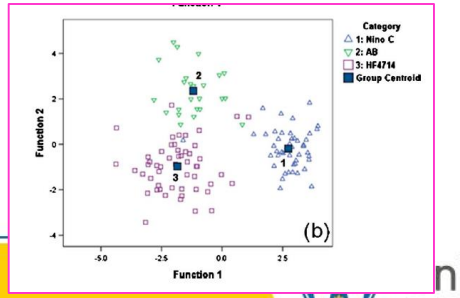
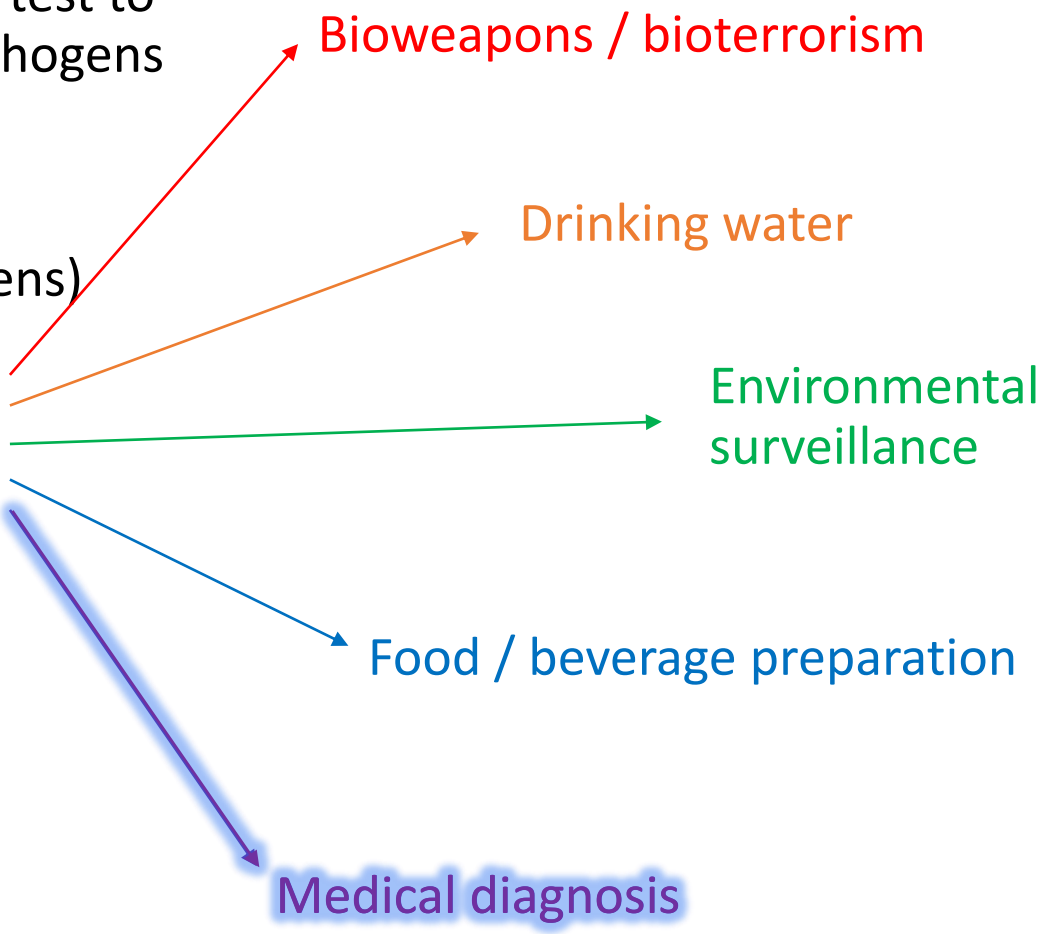
(Received 26 January 2007; accepted 15 March 2007; published online 16 April 2007)



The Reasons?

There did not exist at the time, *and there still is not now*, a diagnostic test to detect and diagnose bacterial pathogens that can be:

- highly-flexible (multiple pathogens)
- very rapid (under 5 minutes)
- robust (field portable)
- relatively simple (minimal prep, performed by a non-expert)
- few to no consumables (biodegradation, cost)
- sensitive
- specific



To the present

Since then, progress has been extensive on:

- the number / variety of species
- sample preparation methods
- hardware setups
- chemometric algorithms
- number of bacteria detectable
- machine learning

To the present

Table 2
A summary of all the bacterial species/strains tested with LIBS.

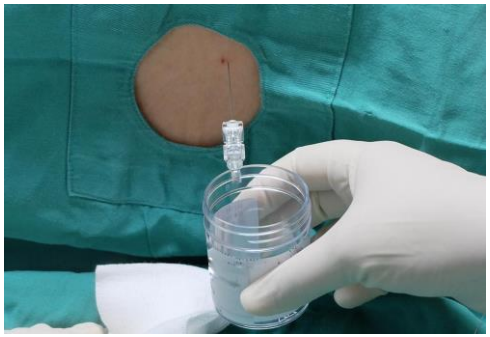
Micro-organism	Reference	Form	Chemometric utilized	Laser wavelength[a]
Acinetobacter baumannii ATCC BAA-1789	[66]	Colony on blood agar	PCA/PLS1	1064
Acinetobacter baylyi	[48]	Pellet, freeze-dried powder	Hyperspace projection of trace elements	810 (fs)
Acinetobacter calcoaceticus [FJ816073][b]	[71]	Colony on glass slide	PCA/PLS-RA	800 (fs)
Arhodomonas sp. [EU308280]	[71]	Colony on glass slide	PCA/PLS-RA	800 (fs)
Bacillus anthracis var. Sterne	[44]	Thin lawn[c] on nylon filter	None	1064
Bacillus anthracis var. Sterne	[38]	Thin lawn on agar, glass slide	PCA/PLS1	1064
Bacillus atrophaeous	[41]	Spore, aerosol stream	None	1064
Bacillus atrophaeous	[52,37]	Dried film on Al disk, steel disk, polycarbonate disk	NN, MLSRA,PLS-DA	1064
Bacillus atrophaeous	[57]	Pellet, freeze-dried powder	SVM	1064
Bacillus aureus	[35]	Spore, EDB trap	None	355
Bacillus cereus 6E1	[29,32]	Thin lawn on silver membrane filter	PCA, linear correlation, and SIMCA	1064
Bacillus cereus ATCC 14603	[57]	Pellet, freeze-dried powder	SVM	1064
Bacillus globigii[d] BG-1	[39,40]	Pellet, freeze-dried powder	None	1064
Bacillus globigii BG-1	[40]	Spore, aerosol stream	None	1064
Bacillus globigii BG-2	[39,40]	Pellet, freeze-dried powder	None	1064
Bacillus globigii BG-2	[40]	Spore, aerosol stream	None	1064
Bacillus globigii var. niger	[29,42,32]	Thin lawn on silver membrane filter	PCA, linear correlation, and SIMCA	1064
Bacillus globigii var. niger	[30]	Continually refreshed dense aerosol cloud (from powder) and aerosol stream	PCA	1064
Bacillus globigii var. niger	[35,68]	Powder on double-sided sticky tape	No, linear correlation, PCA, PLS-DA	1064 × 2 (DP)
Bacillus globigii 168	[43]	Colony (wet) on LB medium	None	532
Bacillus globigii	[47]	Thin film lawn on cellulose nitrate membrane filter	None	810 (fs), 1064
Bacillus globigii	[48]	Pellet, freeze-dried powder	Hyperspace projection of trace elements	810 (fs)
Bacillus globigii	[31]	Dried powder on solid substrate	PCA, HCA, PCA + LDA	1064
Bacillus globigii ATCC 23857	[66]	Colony on blood agar	PCA/PLS1	1064
Bacillus megaterium QM B1551	[43]	Colony (wet) on LB medium	None	532
Bacillus megaterium PV361	[43]	Colony (wet) on LB medium	None	532
Bacillus stearothermophilus ATCC 12979	[57]	Pellet, freeze-dried powder	SVM	1064
Bacillus thurengensis	[39,40]	Pellet, freeze-dried powder	None	1064
Bacillus thurengensis var. kurstaki	[29,32]	Thin lawn on silver membrane filter	PCA, linear correlation, and SIMCA	1064
Bacillus thurengensis var. kurstaki	[44]	Thin lawn on nylon filter	None	1064
Bacillus thurengensis T34	[43]	Colony (wet) on LB medium	None	532
Bacillus thuringiensis ATCC 51912	[57]	Pellet, freeze-dried powder	SVM	1064
Bacillus sp. [GQ392044]	[71]	Colony on glass slide	PCA/PLS-RA	800 (fs)
Bacillus sp. [GQ226038]	[71]	Colony on glass slide	PCA/PLS-RA	800 (fs)
Bacillus sp. [HM026606]	[71]	Colony on glass slide	PCA/PLS-RA	800 (fs)
Enterobacter cloacae [FJ194527]	[71]	Colony on glass slide	PCA/PLS-RA	800 (fs)
Enterobacter cloacae ATCC 13047	[64,67]	Thin lawn on nutrient-free agar	DFA, PLS-DA	1064
Enterobacter sp. [CP000653]	[71]	Colony on glass slide	PCA/PLS-RA	800 (fs)
Enterobacter sp. [GU586319]	[71]	Colony on glass slide	PCA/PLS-RA	800 (fs)

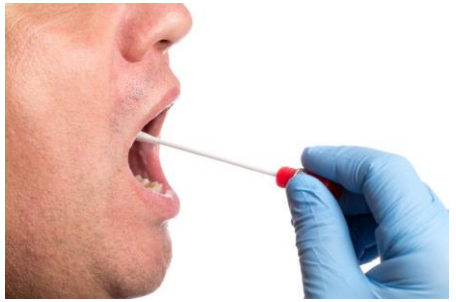
Specimen presentation

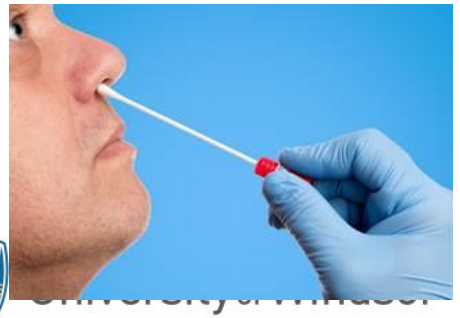
In my research, I am almost completely focused on developing a realistic clinical testing methodology.

Current methods of LIBS bacterial analysis are completely inadequate for this purpose.

Most samples are obtained as fluid specimens, need to perform LIBS on <u>that</u> to be truly rapid.







Outline for rest of talk

1. Explain how we perform LIBS on bacteria in my lab in general

2. Three case studies

    2a. Using the same sample preparation and data analysis

        - **Blood**

        - Urine

    2b. Using a modified sample preparation and data analysis

        - Cerebrospinal fluid

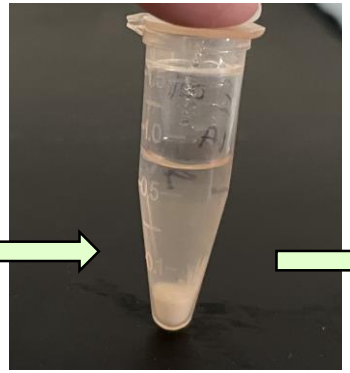
Fiber coupled light collection

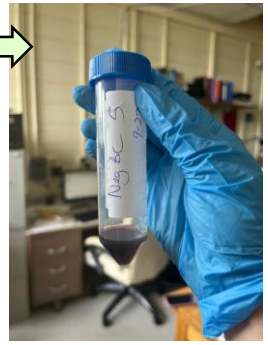
Methodology – Bacterial Growth & Sample Prep

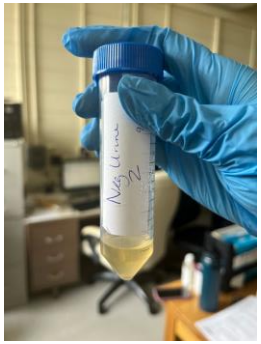
Bacteria cultured on agar plate



Harvested bacteria stored in $M\Omega H_2O$

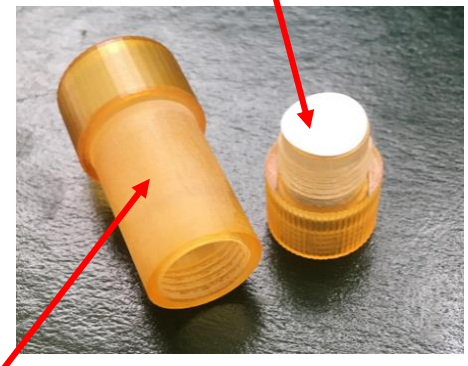
Bacteria-negative specimens collected from hospital



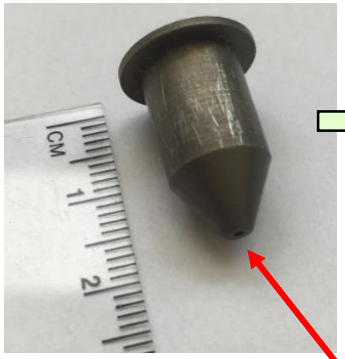


100 µL fluid specimen + 100 µL bacterial suspension pipetted into reassembled apparatus and sealed in centrifuge tube

9.5 mm diameter disposable filter



Disassembled 3D printed centrifuge insert



Aluminum cone with 1 mm diameter aperture at apex

Centrifuge insert assembled with filter & cone

Methodology – Bacterial Growth & Sample Prep

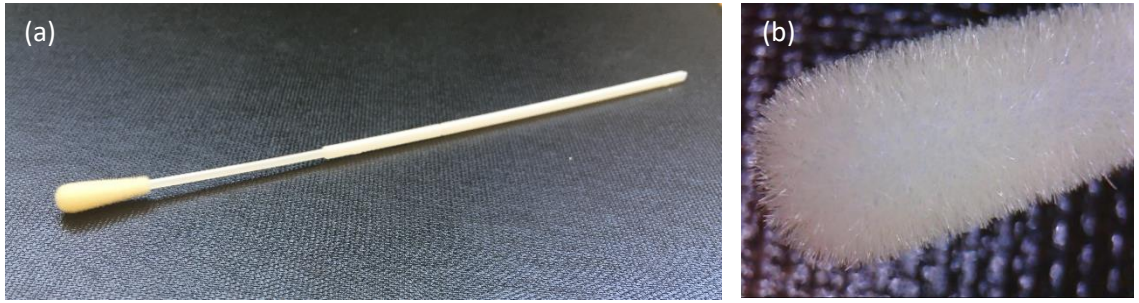


Figure 7.1: (a) Flocked swab used in this work. (b) Flocked swab zoomed-in on the tip.

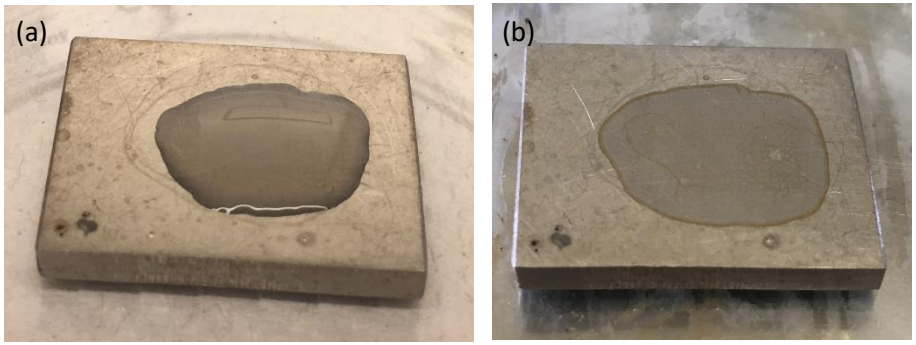

Figure 7.5: (a) 100 μL of E. coli pipetted onto surface of metal plate. (b) Metal plate after heated on hot-plate for 2 minutes 20 seconds at 200 °C. Water has evaporated and film of bacteria is observed.

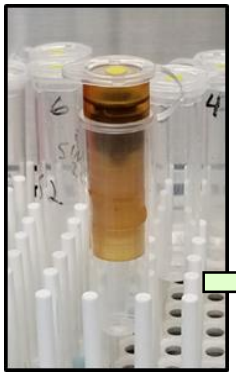
Flocked swab was pre-wet with 10 μL of deionized and swabbed over surface

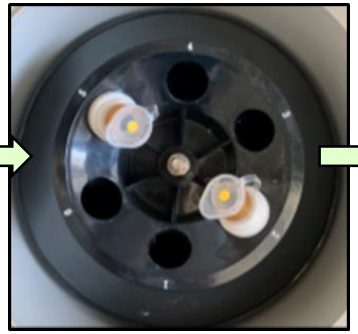
The swab was placed in 1 mL of deionized water and vortexed for 15 seconds. The entire 1 mL was deposited on a filter paper using the insert and metal cone.

Methodology – Bacterial Growth & Sample Prep

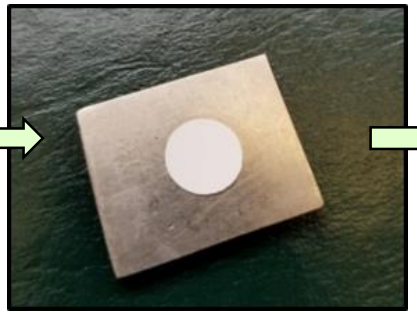


Assembled centrifuge tube insert

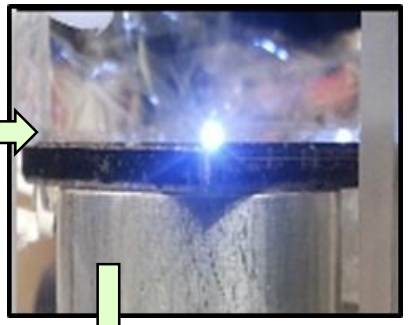
Samples centrifuged at 5000 RPM for five minutes



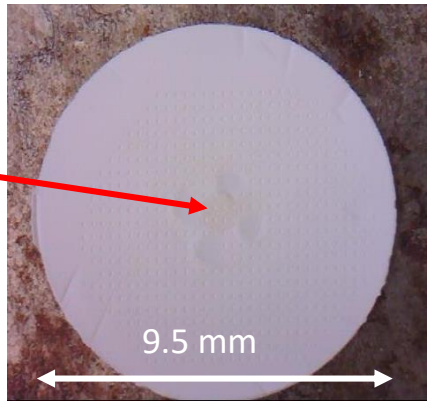
Insert disassembled, filter mounted on steel with double-sided sticky tape

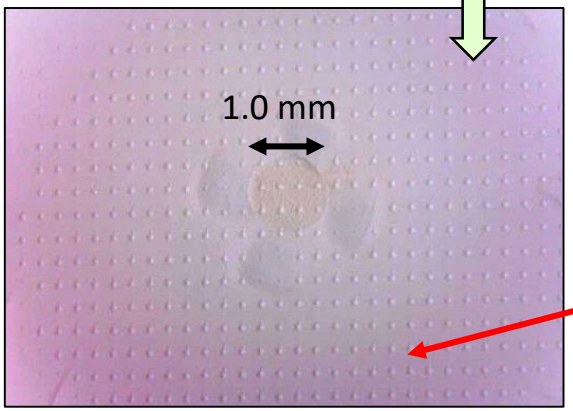


Sample ablated in Ar environment



Filter after centrifugation; bacteria concentrated at the center. We obtain 25-30 LIBS spectra per deposition (could be more)





Magnification of the filter with a rastered array of laser ablation sites

Images of filter after data acquisition

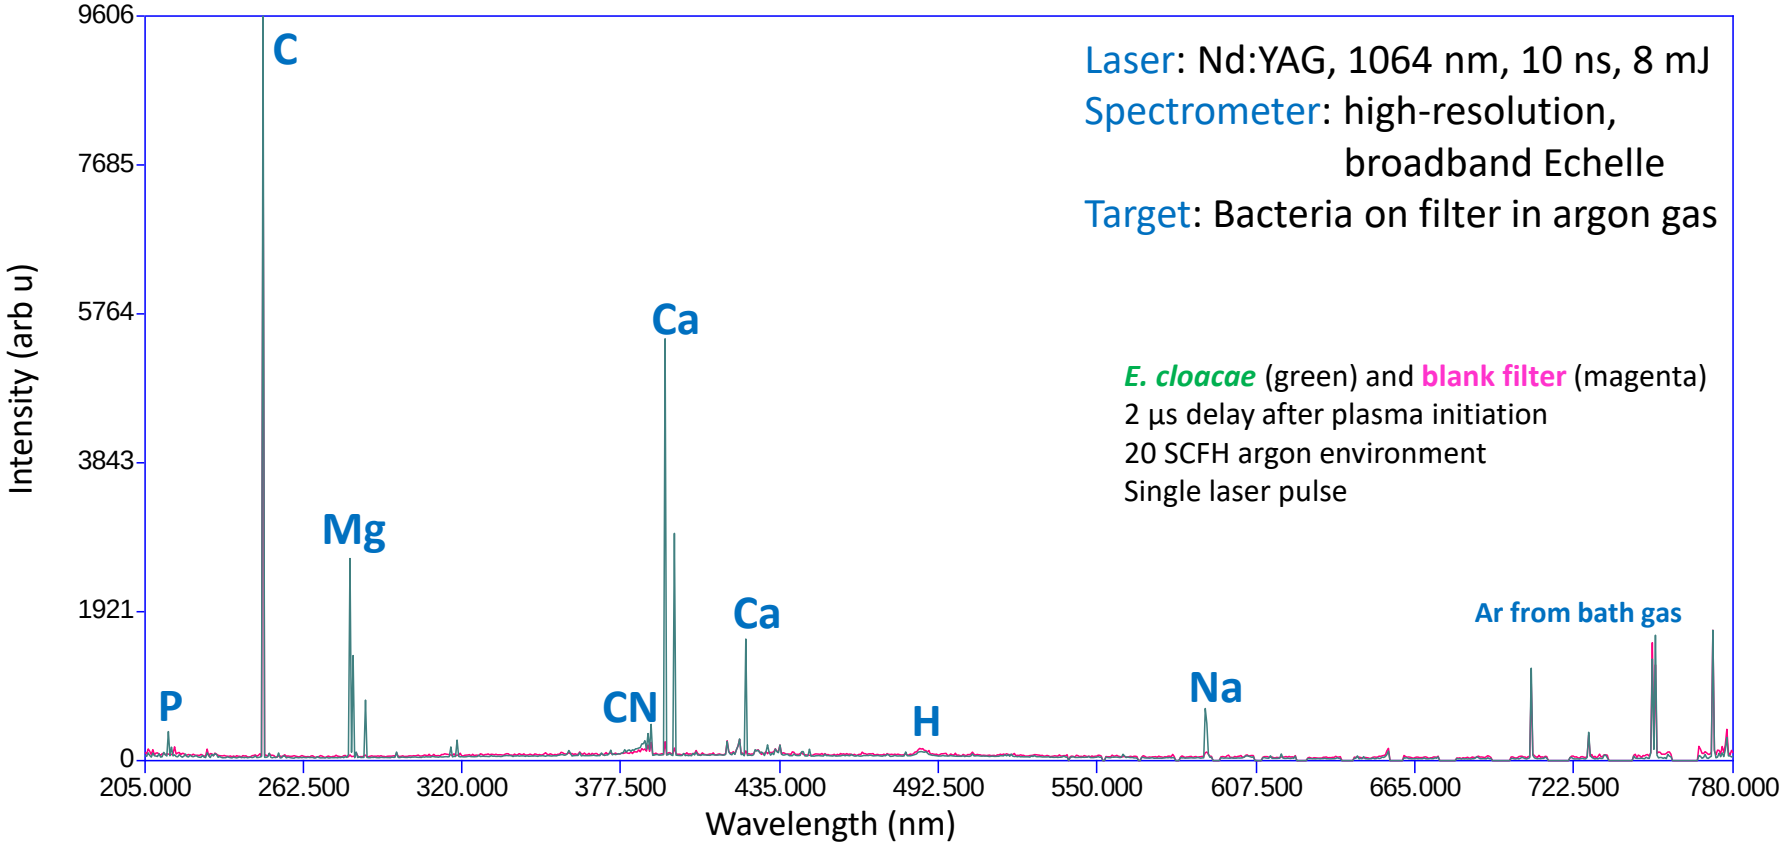
Spectrum From Bacteria

An elemental assay of the bacterial cell composition!



Suggests a real-time method for pathogenic bacterial diagnosis.

Detecting Species in Fluids with Chemometrics

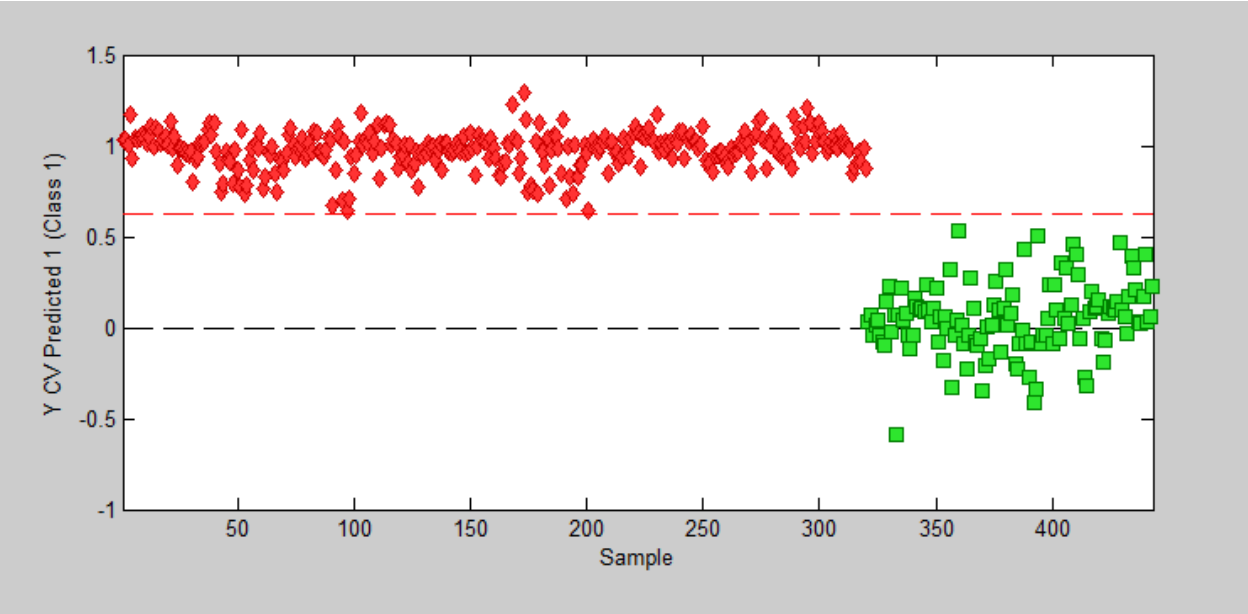
"Ratio Model" consists of:

- 15 emission line intensities from P, C, Mg, Ca, and Na and 92 simple ratios
- 107 total independent variables

PLS-DA on Ratio Model

PLS-DA implemented with PLS_Toolbox (Eigenvector, Inc)

- Run on desktop PC, takes seconds
- Always perform a two-class test and remove entire filters at a time for testing



Diagnosing Species in Fluids with Machine Learning

"Ratio Model" consists of:

- 15 emission line intensities and 92 simple ratios
- 107 independent variables

DFA on Ratio Model

ANN on Ratio Model

PCA-ANN on Ratio Model

PCA-ANN on Full Spectrum Data*

- Started using the **"whole spectrum"** from 200 nm - 590 nm. 42,000 variables.
- Perform unsupervised PCA first (implemented in Python), reduce to 10 PC's.
- Models are trained on 80% of single shot data, 20% reserved for testing. (~15 seconds).

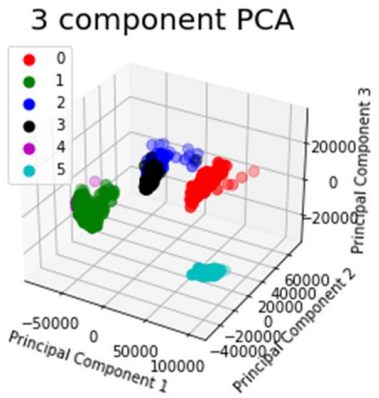
PCA-ANN With Full Spectrum Data			
	E. coli	S. aureus	E. cloacae
Sensitivity	98.04 %	93.27 %	91.23 %
Specificity	97.71 %	97.22 %	96.12 %
Classification Error	2.13 %	4.28 %	6.33 %

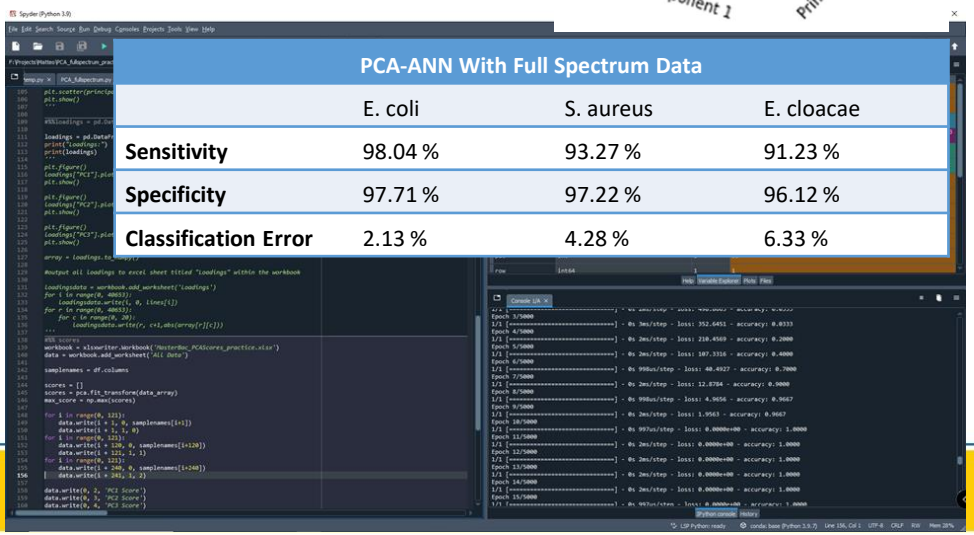
*The full spectrum spans 200 nm – 760 nm, but no lines of interest > 590 nm

Diagnosing Species in Water with Machine Learning

- PCA-ANN custom written in Python
- 42,000 independent variables ⇒ 10 principal components (new independent variables)
- Currently only one hidden layer
- ANN algorithm implemented to optimize the patience and # of hidden nodes
- Models are trained on 80% of single shot data, 20% reserved for testing.

- After PCA, spectra were randomized to demonstrate the ANN was not fitting noise (random classification of cases)





PCA-ANN With Full Spectrum Data

	E. coli	S. aureus	E. cloacae
Sensitivity	98.04 %	93.27 %	91.23 %
Specificity	97.71 %	97.22 %	96.12 %
Classification Error	2.13 %	4.28 %	6.33 %

Blood (sepsis)

Sepsis (bacterial blood infection) is a highly dangerous infection and is a common nosocomial (hospital acquired) infection.

Sepsis is not always caused by bacterial infection, but many cases are bacterial in origin.

A blood culture is required for the diagnosis of sepsis, but not all blood cultures will produce a positive test result.

Antibiotics are the preferred treatment for sepsis, but even with the best treatment the mortality for patients who have reached septic shock is no better than 50%.

The time it takes to initiate effective antimicrobial therapy is the single strongest predictor of patient outcome, with every hour of delay increasing patient mortality.

E. Whitnack, Sepsis, in: N.C. Engleberg, V.J. DiRita, T. Dermody, M. Schaechter (Eds.), Mechanisms of Microbial Disease, 3rd ed, Lippincott Williams & Wilkins, 2007, pp. 564–572.

A. Kumar, D. Roberts, K.E. Wood, B. Light, J.E. Parrillo, et al., Duration of hypotension before initiation of effective antimicrobial therapy is the critical determinant of survival in human septic shock, Crit. Care Med. 34 (2006) 1589–1596.

Blood (sepsis)

The standard diagnostic blood cultures are slow and labor intensive, usually requiring a two-step procedure:

1) an initial culture taking up to 120 h

2) a 24-48 h subculture to identify the pathogens detected in a positive initial culture.

Automated blood culture system

Culturing and diagnosis done manually

Detecting Infection in Blood with a PLS-DA

Bacterial-negative specimens obtained from Windsor Regional Hospital with the anticoagulant sodium polyanetholesulfonate (SPS) present.

Five different blood samples from different patients were provided to account for the difference between patient physiology.

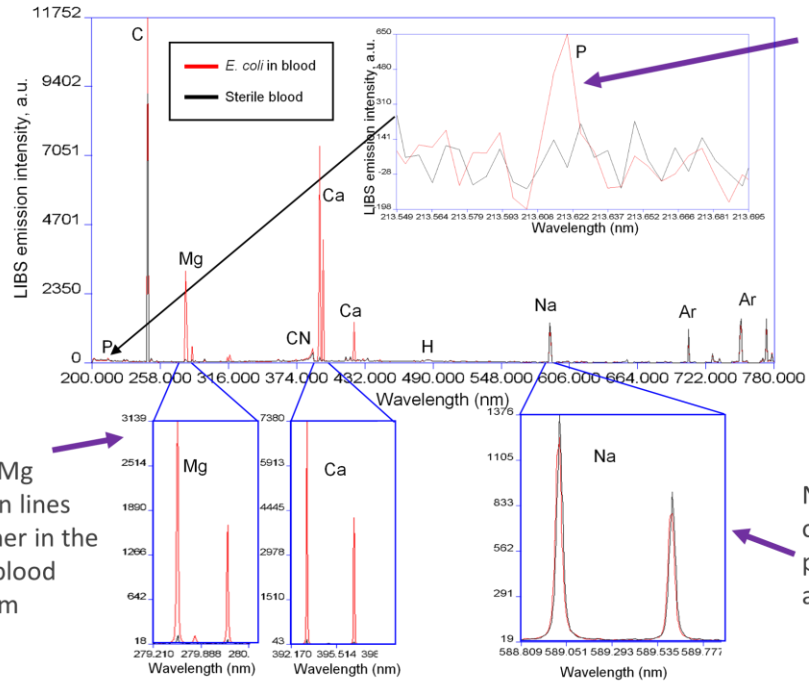
Specimens were vortex-mixed prior to handling to insure the redistribution of any suspended particles.

DETECTION IN BLOOD (individual spectra)

96.3% sensitivity – 600 bacterial spectra
98.6% specificity – 206 blood spectra
11,000 cells / spectrum

DETECTION IN BLOOD (spectra added)

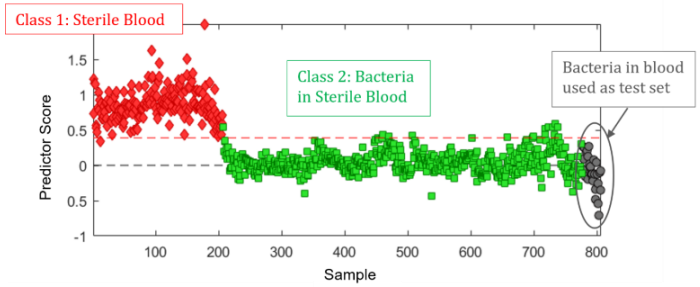
19 of 19 filters positive, 100% sensitivity
7 of 7 filters negative, 100% specificity



P line is small in the spiked blood, but not present in the sterile blood

Ca and Mg emission lines are higher in the spiked blood spectrum

Na emission observed is partially due to anticoagulant



Prepared Samples:

- 5 filters each of *S. aureus*, *E. coli*, *E. cloacae*
- 4 filters of *P. aeruginosa*
- 7 filters of sterile blood
- 30 LIBS laser shots from each deposition

Diagnosing Infection in Blood with PCA-ANN

Urine (UTI)

UTI (urinary tract infections) are one of the most common infections in adult women, with up to 50% of women having experienced at least one UTI in their lifetime and upwards of 10% of women experiencing at least one UTI annually.

In 2007, UTI resulted in approximately 8.6 million health care visits in the United States with an estimated cost of 1.6 billion US dollars.

In addition to the prevalence in the population, UTI are also the most common nosocomial infection, with up to 80% of hospital-acquired UTI associated with the use of a bladder catheter.

Even a single catheterization can lead to UTI due to contamination of the catheter tip.

T.K. Price, E.E. Hilt, T.J. Dune, E.R. Mueller, A.J. Wolfe, L. Brubaker, Urine trouble: should we think differently about UTI?, Int. Urogynecol. J. 29 (2018) 205-210,

Detecting Infection in Urine with a PLS-DA

Bacterial-negative urine specimens obtained from Windsor Regional Hospital.

Urine specimens from four different patients were characterized to account for differences in patient physiology.

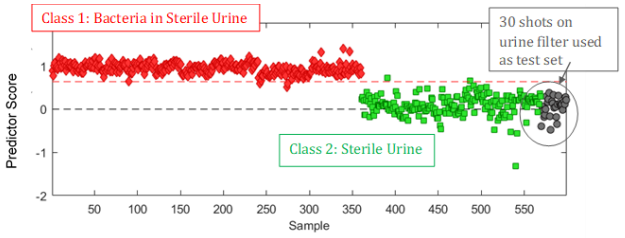
Specimens were vortex-mixed prior to handling to insure the redistribution of any suspended particles.

DETECTION IN URINE (individual spectra)

98.9% sensitivity – 360 bacterial spectra
100% specificity – 240 urine spectra
11,000 cells per spectrum

DETECTION IN URINE (spectra added)

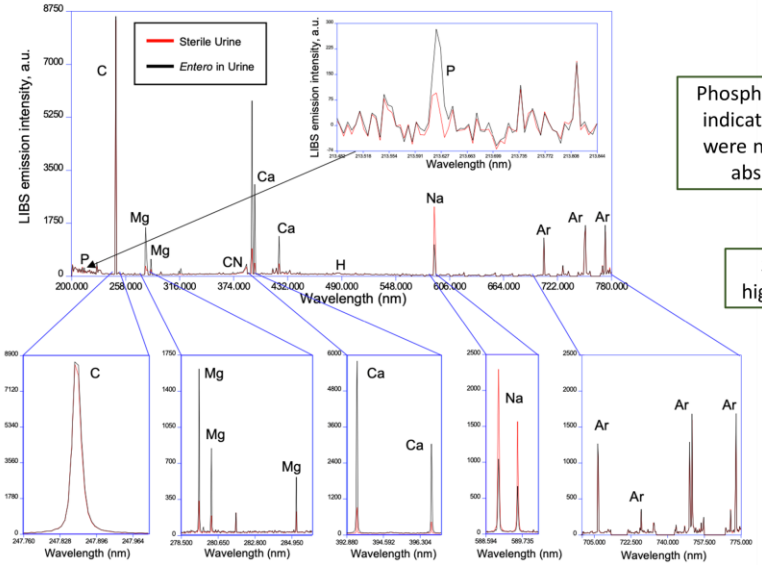
12 of 12 filters positive, 100% sensitivity
8 of 8 filters negative, 100% specificity



Strong carbon emission is predominantly from the nitrocellulose filter

Magnesium lines are greater in spiked urine, an indication of bacteria

Calcium lines higher in spiked urine samples, likely due to bacteria



Phosphorus lines are highly indicative of bacteria, and were never present in the absence of bacteria

Sodium emission higher in sterile urine

Argon lines are from the chamber environment where the samples are shot in

Prepared Samples:

- 4 filters each of *S. aureus*, *E. coli*, *E. cloacae*
- 8 filters of sterile urine
- 30 LIBS laser shots from each deposition

Diagnosing Infection in Urine with PCA-ANN

Cerebrospinal Fluid (meningitis)

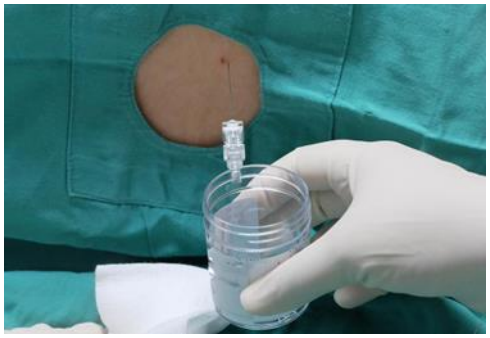
Cerebrospinal fluid (CSF) is the fluid the brain, cranium, and spinal cord are bathed in.

Meningitis is an infection of the brain and spinal cord's protective layers (cells in CSF).

Meningitis may be viral or bacterial in nature.

Delays and inappropriate antibiotic use can lead to severe complications, including irreversible brain damage or death.

The gold standard for diagnosis is a spinal tap (lumbar puncture) to remove **cerebrospinal fluid (CSF)** followed by culture, serology, and analysis.



Slane, Valori H. and Chandrashekhar G. Unakal. “Tuberculous Meningitis.” StatPearls, StatPearls Publishing, 18 November 2022.
Telano, Lauren N. and Stephen Baker. “Physiology, Cerebral Spinal Fluid.” StatPearls, StatPearls Publishing, 4 July 2023.

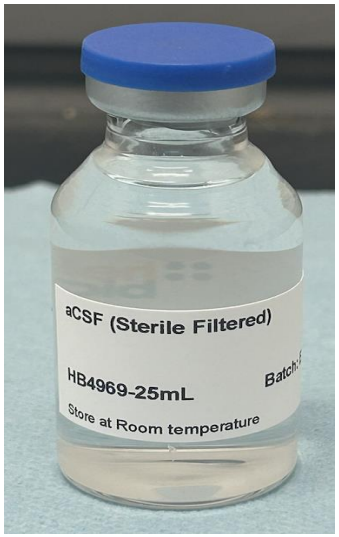
Cerebrospinal Fluid (meningitis)

Spinal taps are rarely performed in Windsor.

Artificial cerebrospinal fluid was used in this study (**aCSF**).

Artificial cerebrospinal spinal fluid (aCSF) closely matches the electrolyte concentrations of actual CSF and is prepared from analytical grade reagents and high purity water.

Ion	Concentrations (mM)
Na^+	150
K^+	3.0
Ca^{2+}	1.4
Mg^{2+}	0.8
P^{3-}	1.0
Cl^-	155

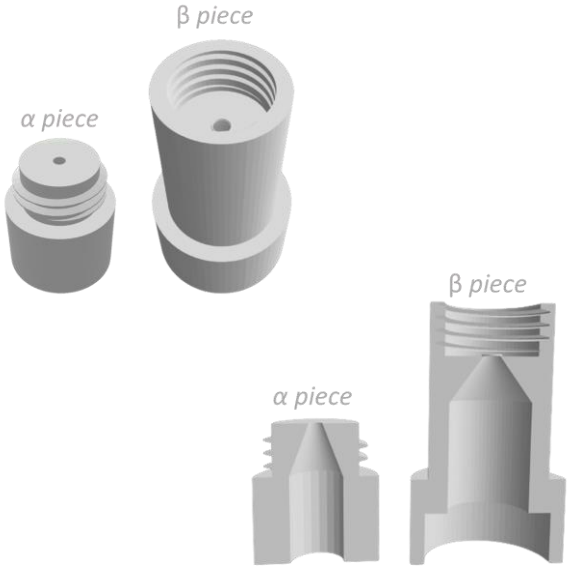


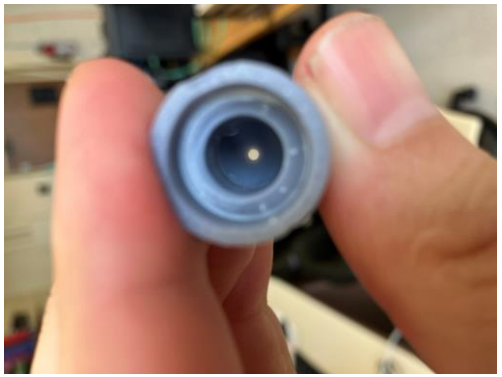
New Apparatus Design

Two components, with a built-in concentration cone.

- ✓ Concentrates bacteria in a 1 mm diameter circle
- ✓ The ridge on the aperture of β piece prevents bacterial escape, allowing only water and ions to diffuse
- ✓ Indent created on filter is more easily identifiable by the LIBS apparatus and seals bacteria

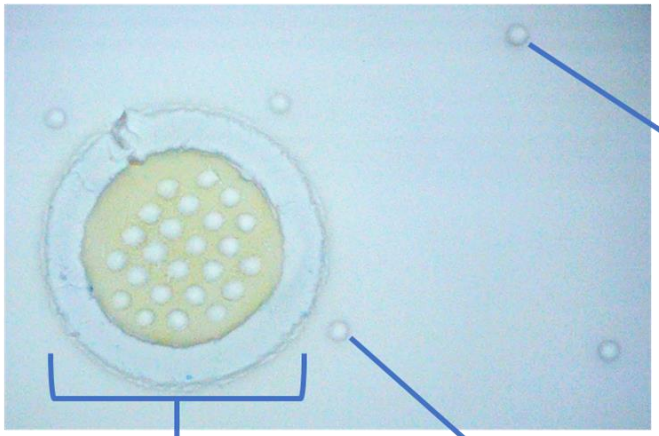
Stronger bacterial signal and more reproducible data





New Apparatus Data

nitrocellulose filter
(0.45 µm pore size)

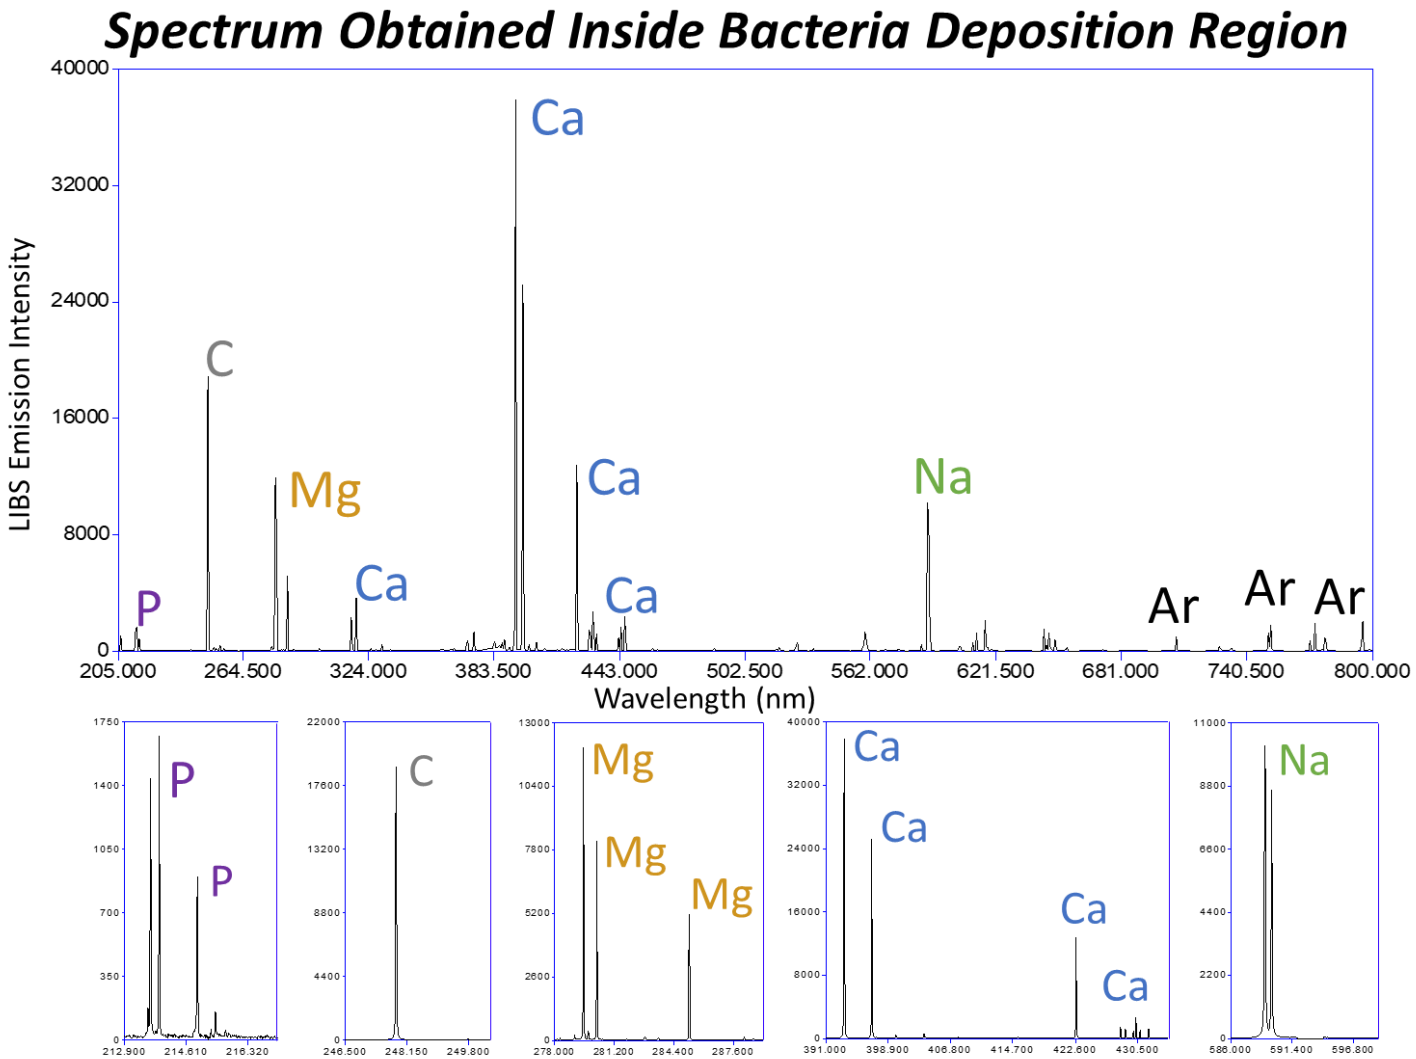


Laser shot obtained far from deposition region and near edge of filter or "Far-Out"

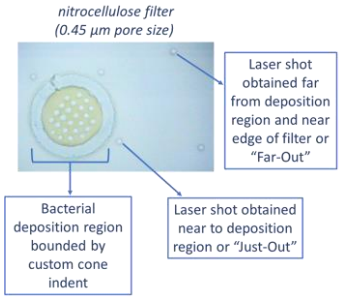
Bacterial deposition region bounded by custom cone indent

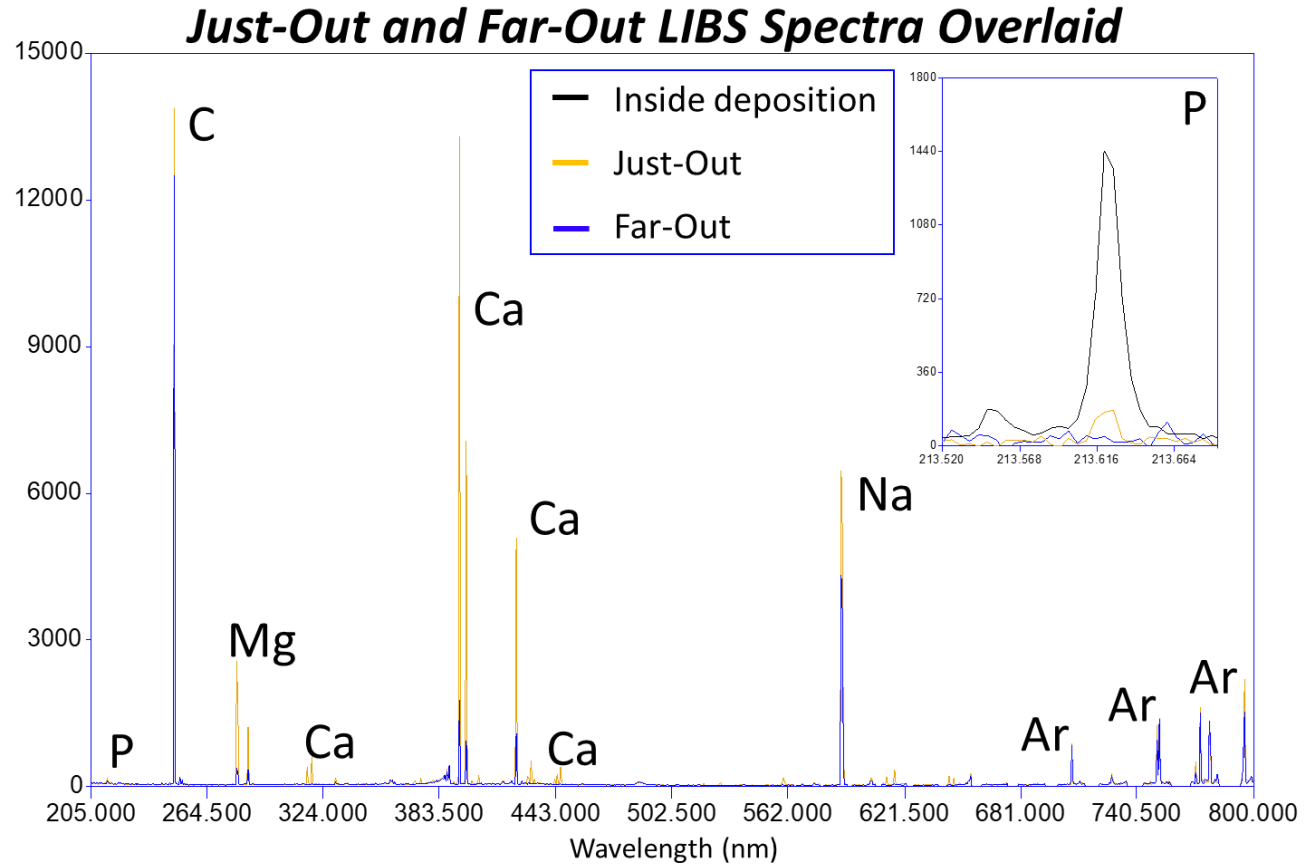
Laser shot obtained near to deposition region or "Just-Out"

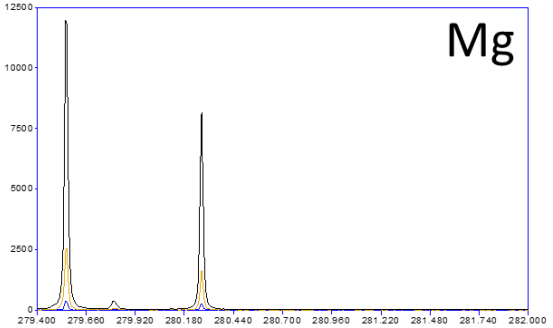
New Apparatus Data

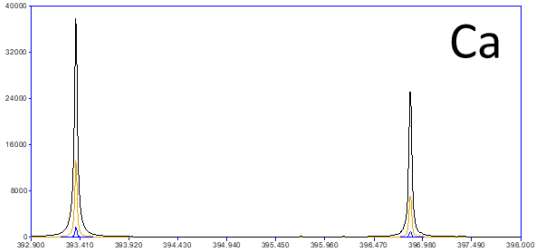


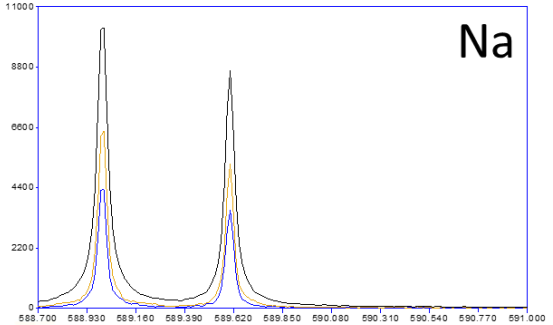
New Apparatus Data





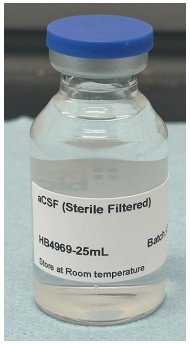






University of Windsor

Detecting Infection in aCSF with a PLS-DA



Bacterial-negative aCSF specimens procured from a biochem supply vendor

Prepared Samples:

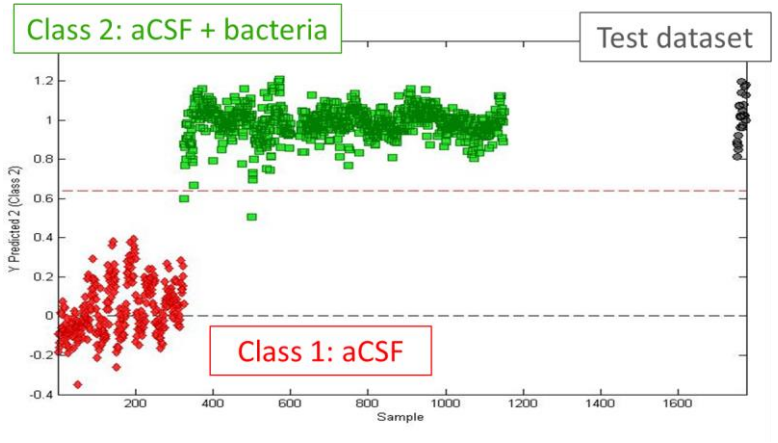
- 11 filters each of *S. aureus*, *E. coli*, *M. smegmatis*
- 13 filters of sterile aCSF
- 25 LIBS laser shots from each deposition

DETECTION IN URINE (individual spectra)

99.8% sensitivity – 825 bacterial spectra
100% specificity – 325 urine spectra
11,000 cells per spectrum

DETECTION IN URINE (spectra added)

33 of 33 filters positive, 100% sensitivity
13 of 13 filters negative, 100% specificity



Diagnosing Infection in aCSF with PCA-ANN

Bacterial-negative aCSF specimens procured from a biochem vendor

Prepared Samples:

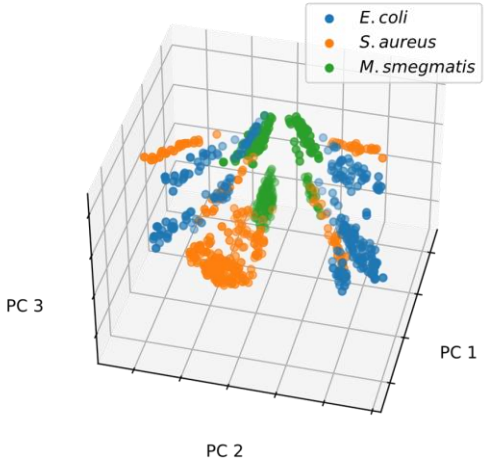
- 11 filters each of *S. aureus*, *E. coli*, *M. smegmatis*
- 13 filters of sterile aCSF
- 25 LIBS laser shots from each deposition

Internal cross-validation (80:20 split) randomly selects 20% of the dataset to be tested against remaining 80% of spectra.

80:20 Cross-Validation Test Results				
	E. coli	*S. aureus*	*M. smegmatis*	Average
Sensitivity	95.8 %	96.0 %	100.0 %	97.2 %
Specificity	98.2 %	98.0 %	99.7 %	98.6 %
Classification Accuracy	97.4 %	97.3 %	99.8 %	98.2 %

External validation tests individually compare one filter (25 spectra) against left over spectra.

External Validation Test Results				
	E. coli	*S. aureus*	*M. smegmatis*	Average
Sensitivity	74.6 %	71.1 %	99.5 %	81.7 %
Specificity	87.6 %	87.9 %	97.0 %	90.9 %
Classification Accuracy	83.3 %	82.3 %	97.9 %	87.8 %



The first three PC scores were plotted to visualize the variance in the data

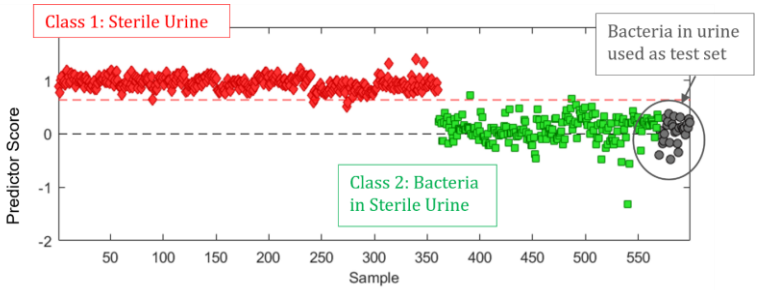
Conclusions

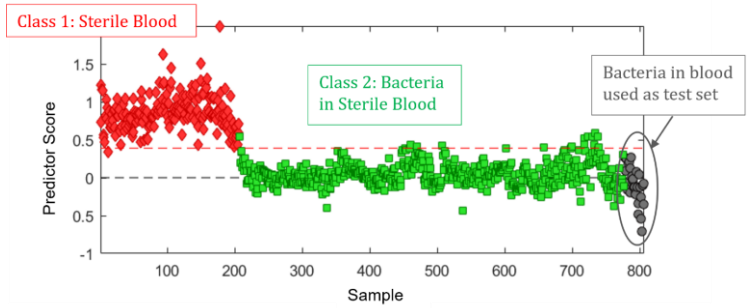
- Bacteria can be **detected** (PLSDA) and **diagnosed** (PCA-ANN) in blood, urine, and CSF.

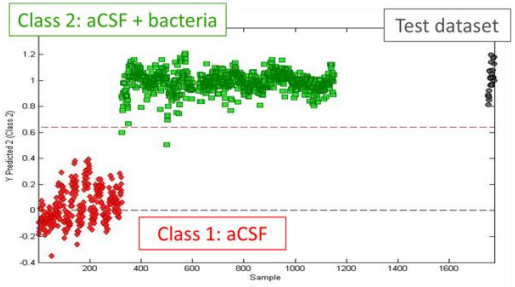
PCA-ANN With Full Spectrum Data (Urine)			
	S. aureus	E. coli	E. cloacae
Sensitivity	100 %	100 %	91.67 %
Specificity	100 %	95.83 %	100 %
Classification Error	0.00 %	2.09 %	4.17 %

PCA-ANN With Full Spectrum Data (Blood)				
	S. aureus	E. coli	E. cloacae	P. aeruginosa
Sensitivity	100 %	100 %	100 %	100 %
Specificity	100 %	100 %	100 %	100 %
Classification Error	0.00 %	0.00 %	0.00 %	0.00 %

PCA-ANN With Full Specrum Data (aCSF)				
	E. coli	*S. aureus*	*M. smegmatis*	Average
Sensitivity	95.8 %	96.0 %	100.0 %	97.2 %
Specificity	98.2 %	98.0 %	99.7 %	98.6 %
Classification Accuracy	97.4 %	97.3 %	99.8 %	98.2 %

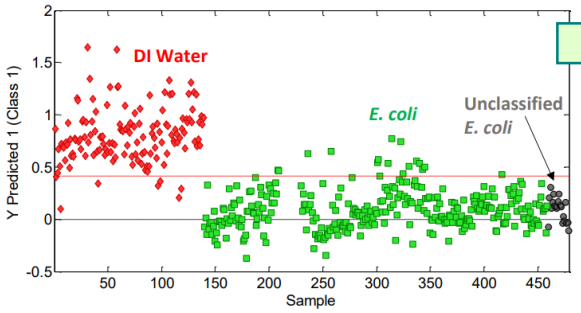




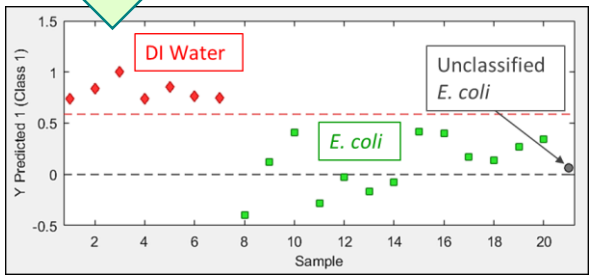


Conclusions

- Adding spectra improves discrimination in PLSDA
  - Detection of bacteria in water, blood, urine, and aCSF improved; **sensitivity = 100%**, **specificity = 100%**
- Rigorous cleaning of cone & usage of ultrapure water reduces background signal



Adding 30 single-shot spectra to create one measurement per filter improves classification in PLSDA



- Using PCA-ANN on full spectrum data provides the best results for discrimination between bacterial species (using 80:20 split)
- Average sensitivity = **94 %**
- Average specificity = **96 %**

PCA-ANN With Full Spectrum Data			
	E. coli	S. aureus	E. cloacae
Sensitivity	98.04 %	93.27 %	91.23 %
Specificity	97.71 %	97.22 %	96.12 %
Classification Error	2.13 %	4.28 %	6.33 %

Approximate increase from DFA ≈ 30 % (sensitivity), 16% (specificity)

Future Work

Improve external validation using PCA-ANN for bacterial species

- New 3D-printed centrifuge insert with integrated concentration cone help to improve signal-to-noise – revisit blood/urine.
- Work to further optimize the PCA-ANN algorithm (adding hidden layers?)
- Determine what is causing the “between-filter” variance in the measurements

Discrimination of lower concentrations of cells to find limit of identification (LOI)

- Engage microbiology students to investigate the behavior of cells in clinical specimens

Extend analysis to other bacterial strains

- *Mycobacterium tuberculosis* and *Streptococcus mitis*

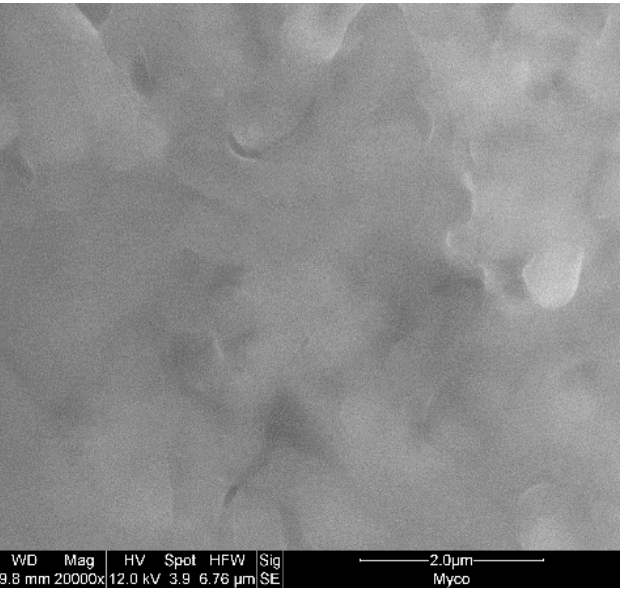
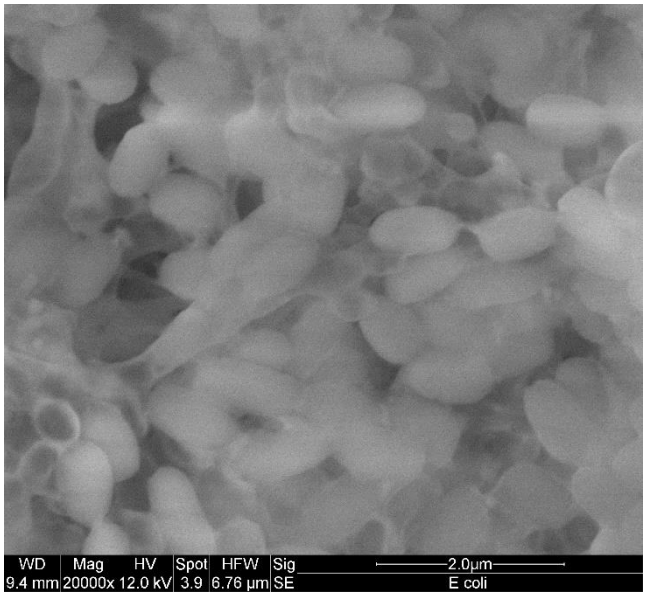
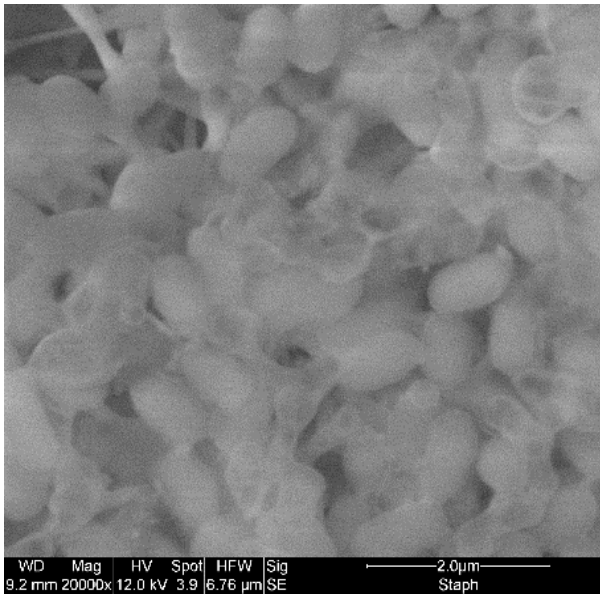
M. smegmatis

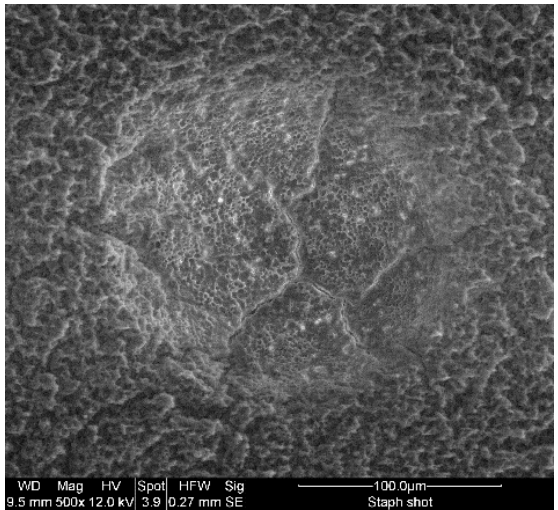


E. coli



S. aureus

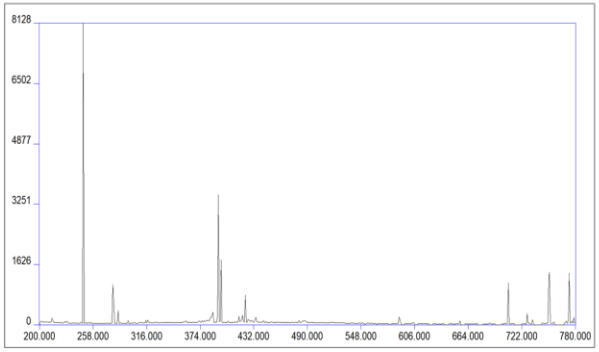




PCA-ANN Results – Identifying Bacteria

GOAL: Classify the species of bacteria in urine

Input: Entire LIBS spectrum from 200 nm to 590 nm (42,000 variables)



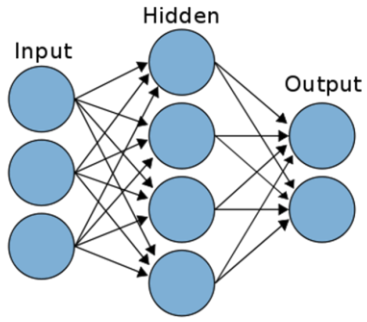
12 spiked urine filters x 30 spectra/filter

PCA: Spectrum is reduced to 10 principal components (PC) scores, through the use of a Python code developed from several libraries

1	2	3	4	5	6	7	8	9	10

Python libraries used: *sklearn.decomposition*, *Pandas*, *Numpy*, and *mpl_toolkits*

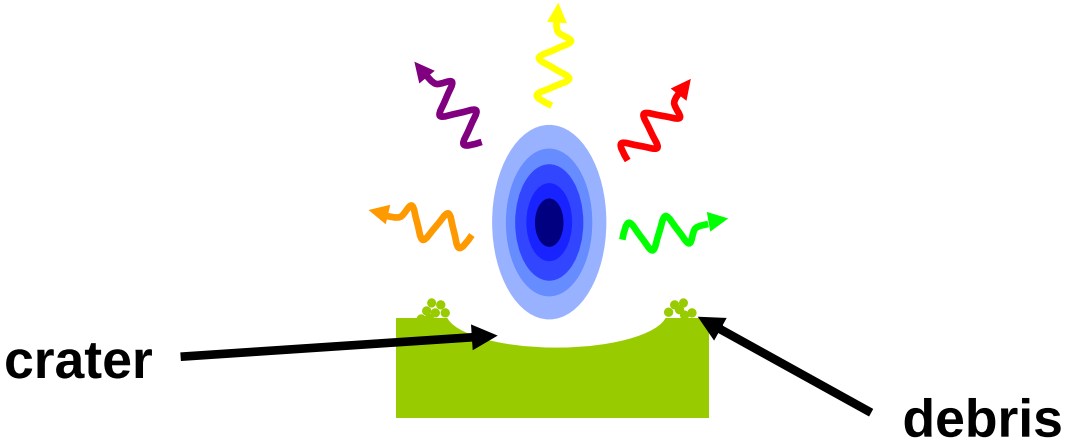
ANN: Neural network developed on Python code relates 10 PC scores to bacterial species



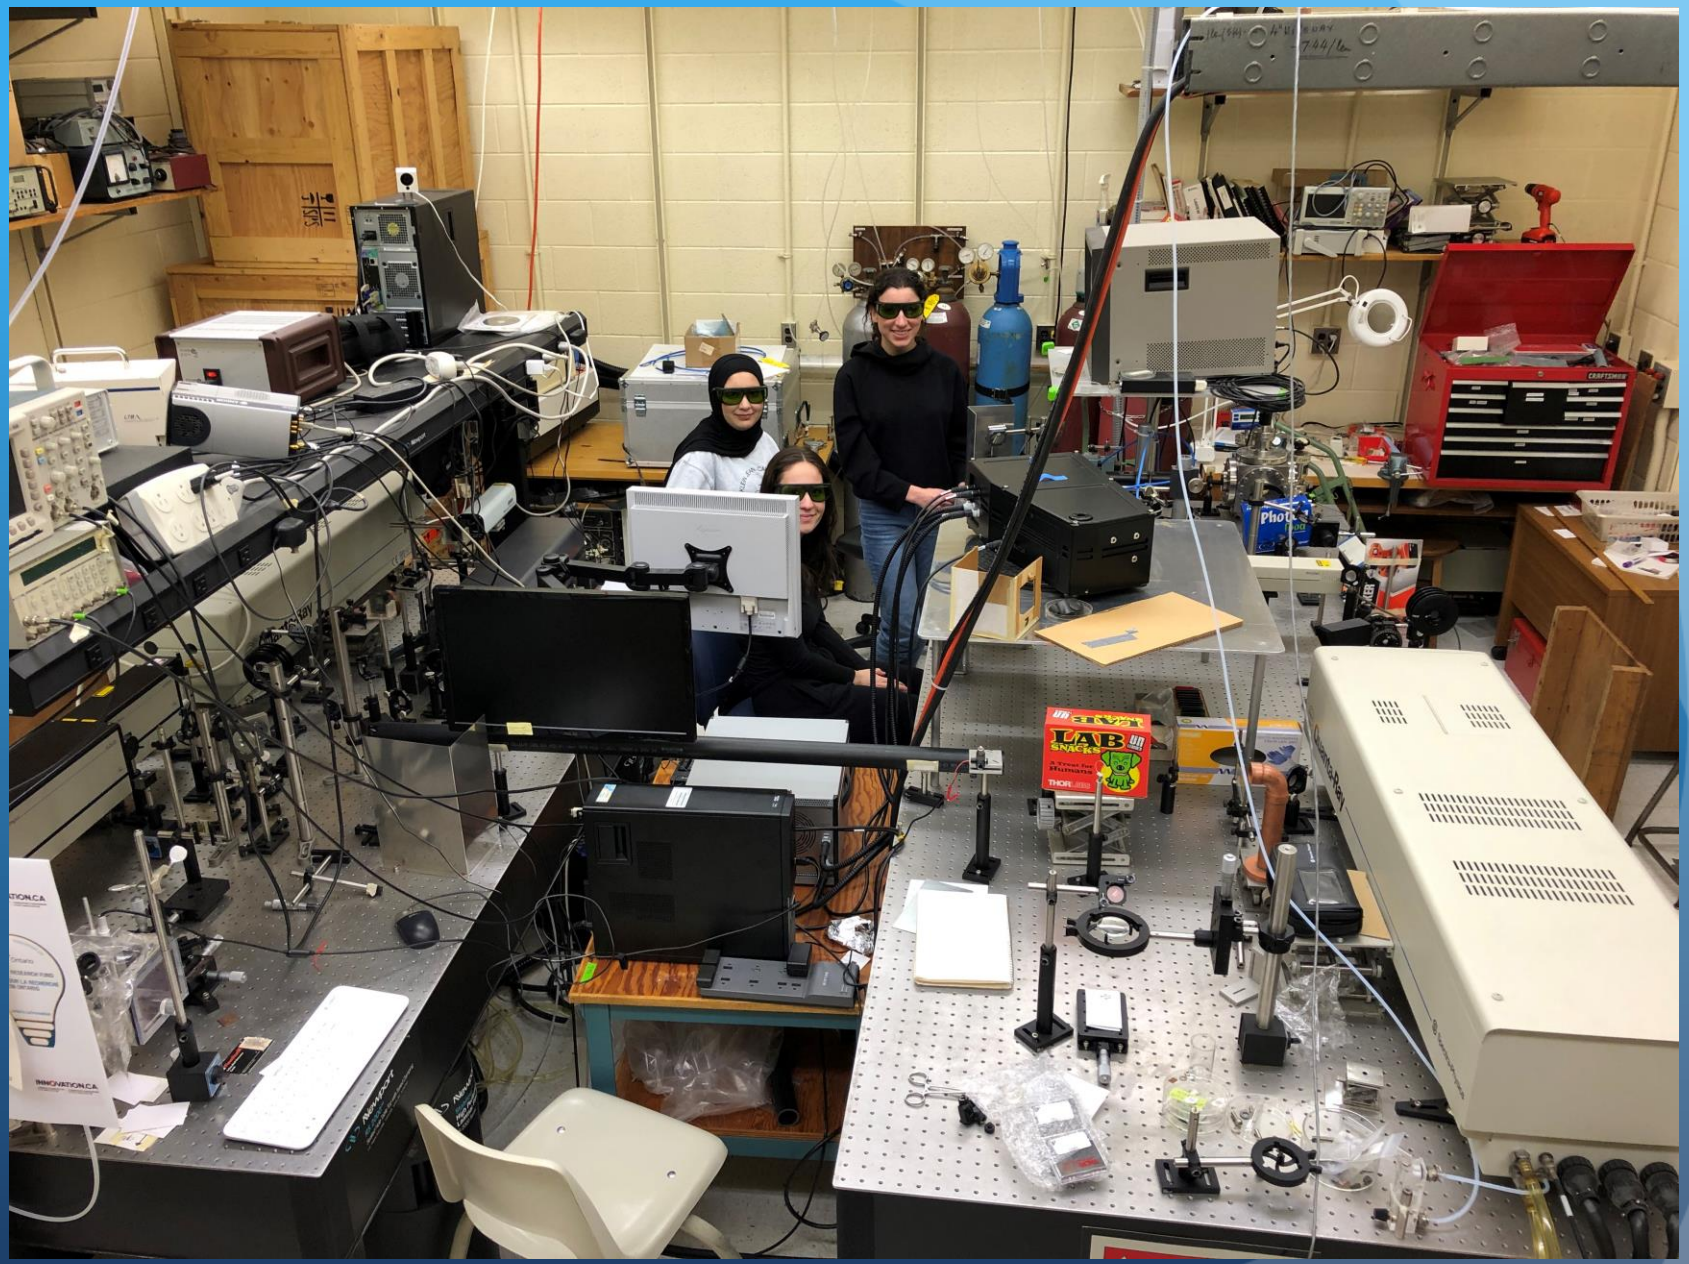
Python libraries used: *Pandas*, *Numpy*, *Tensorflow*, and *Scikit-Learn*

4) expansion and element specific emission (atomic or ionic)

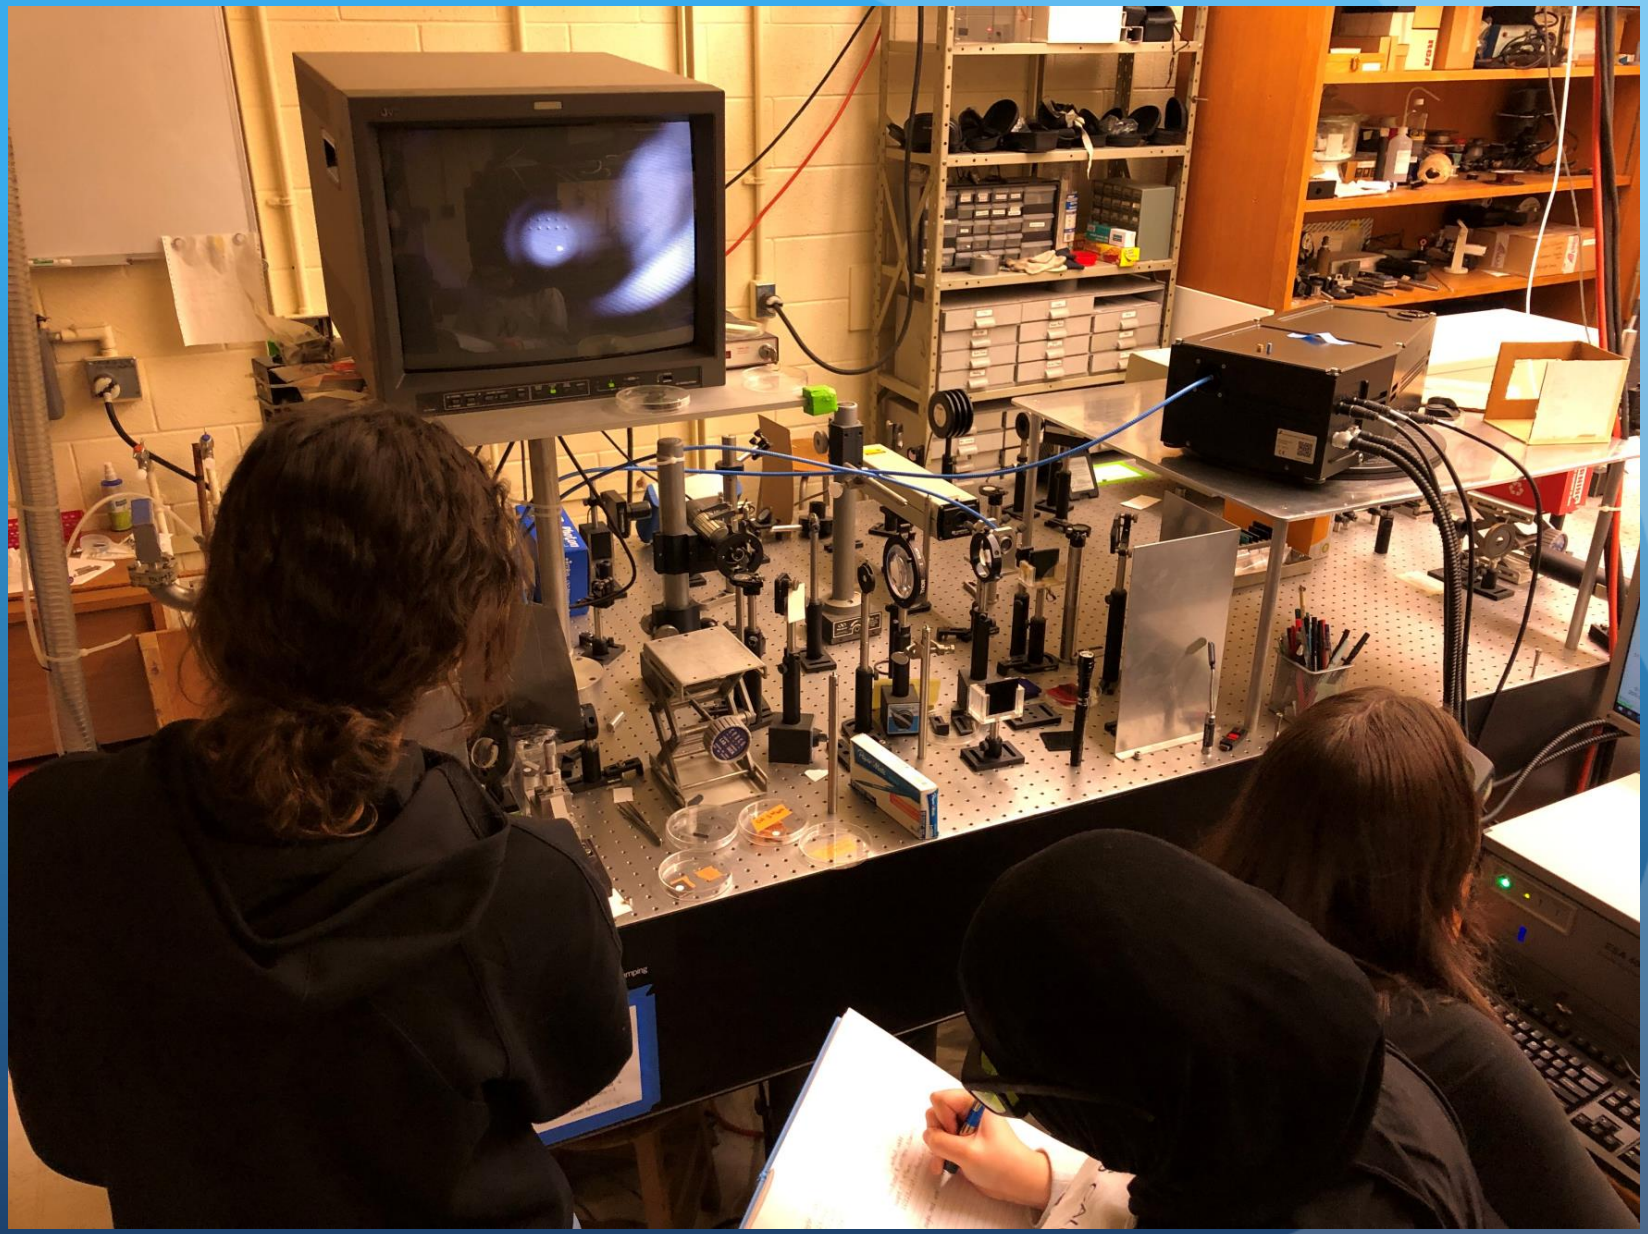
spontaneous emission as atoms/ions decay to ground state



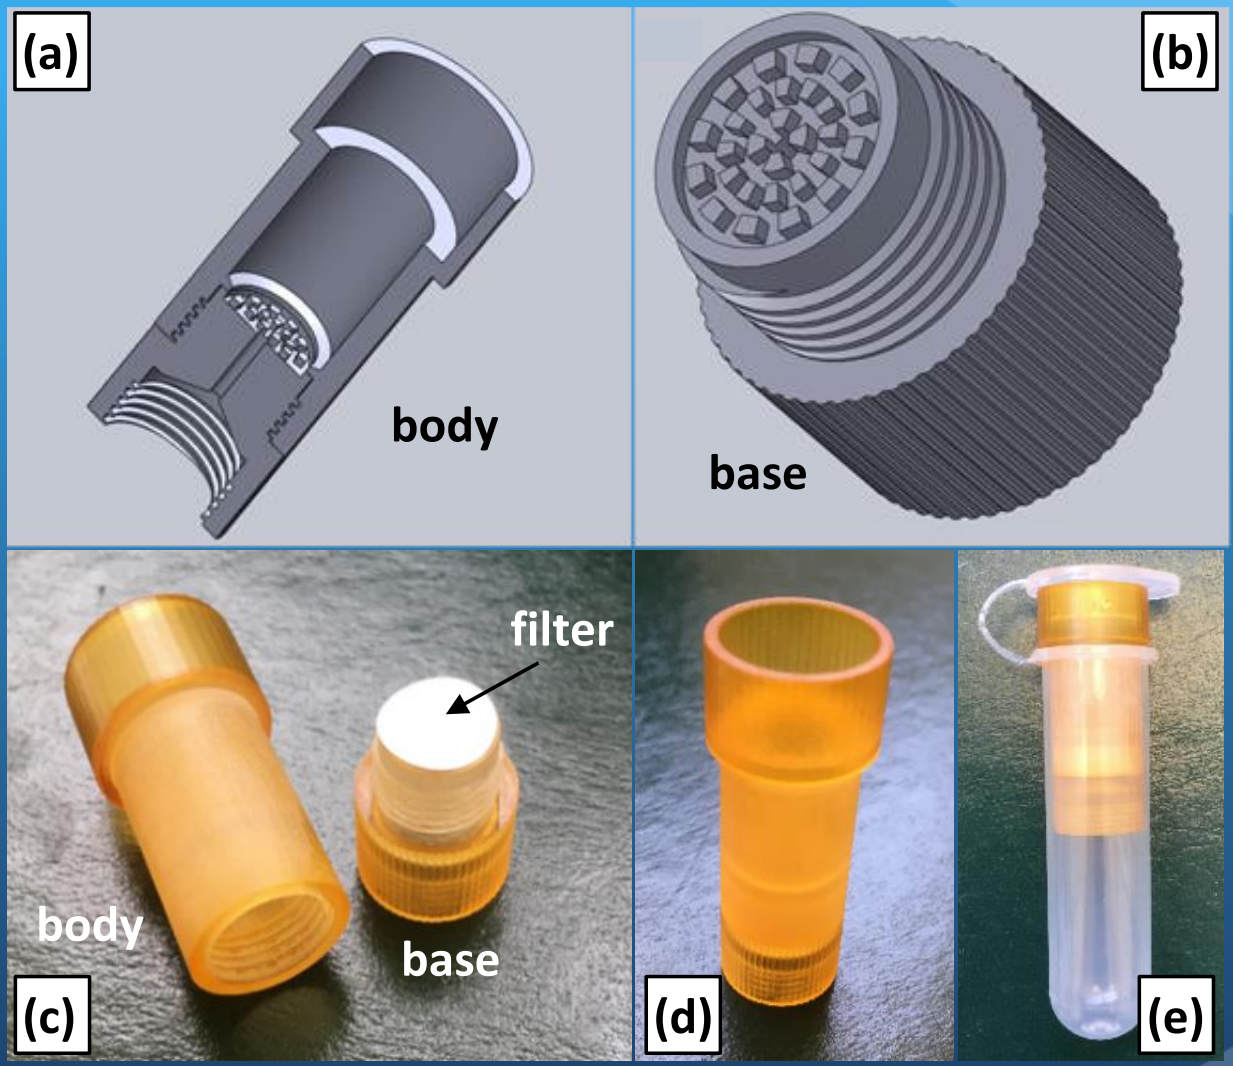
- The dynamic evolution of the plasma plume is then characterized by a fast expansion and subsequent cooling.
- Approximately 1 microsecond after the ablation pulse, spectroscopically narrow atomic/ionic emissions may be identified in the spectrum.



LAB
SNACKS



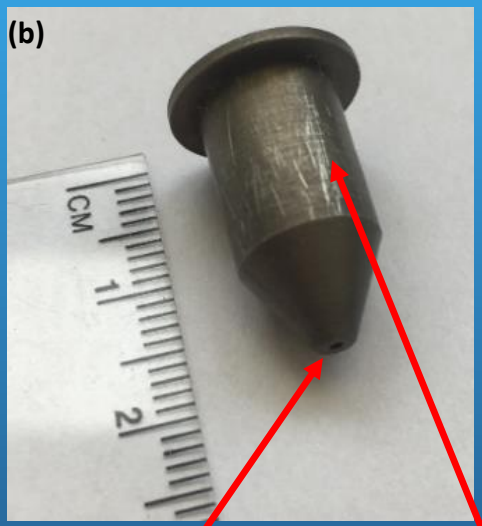
The Centrifuge Insert



Concentrating Bacteria With a Cone

19 mm long Al cone

Centrifuge tube cap presses cone into filter

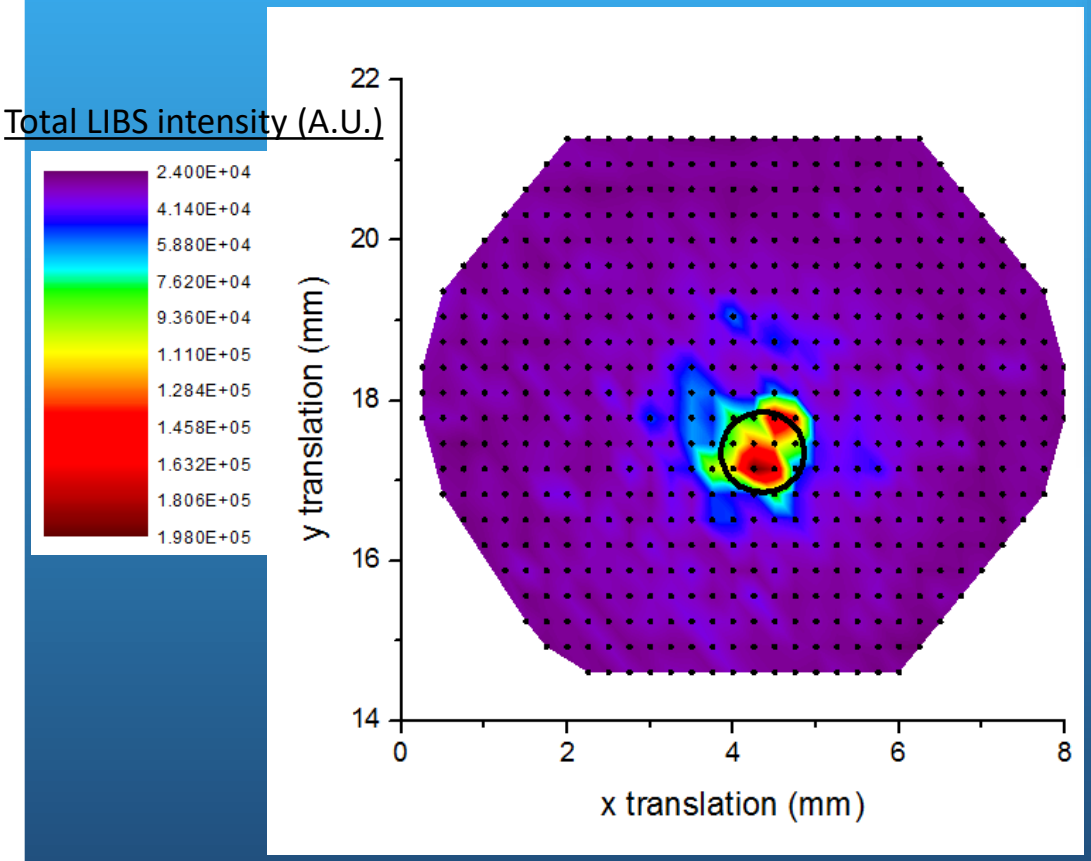


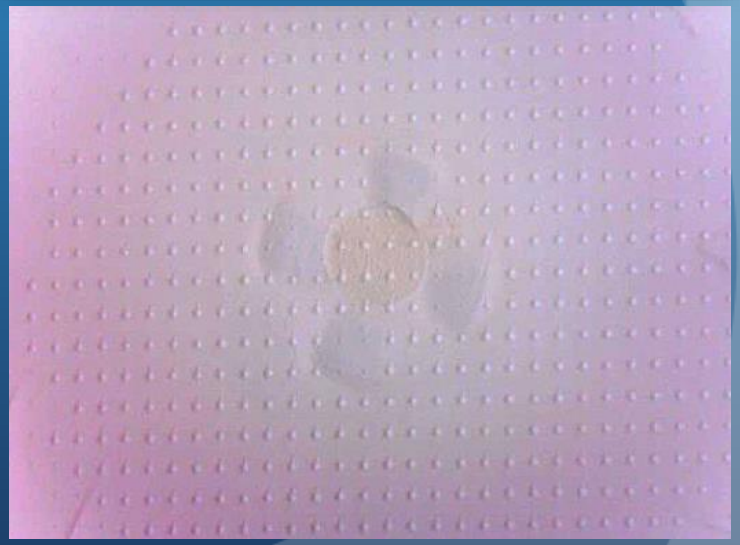
1 mm hole at apex

Holds 1 mL of fluid

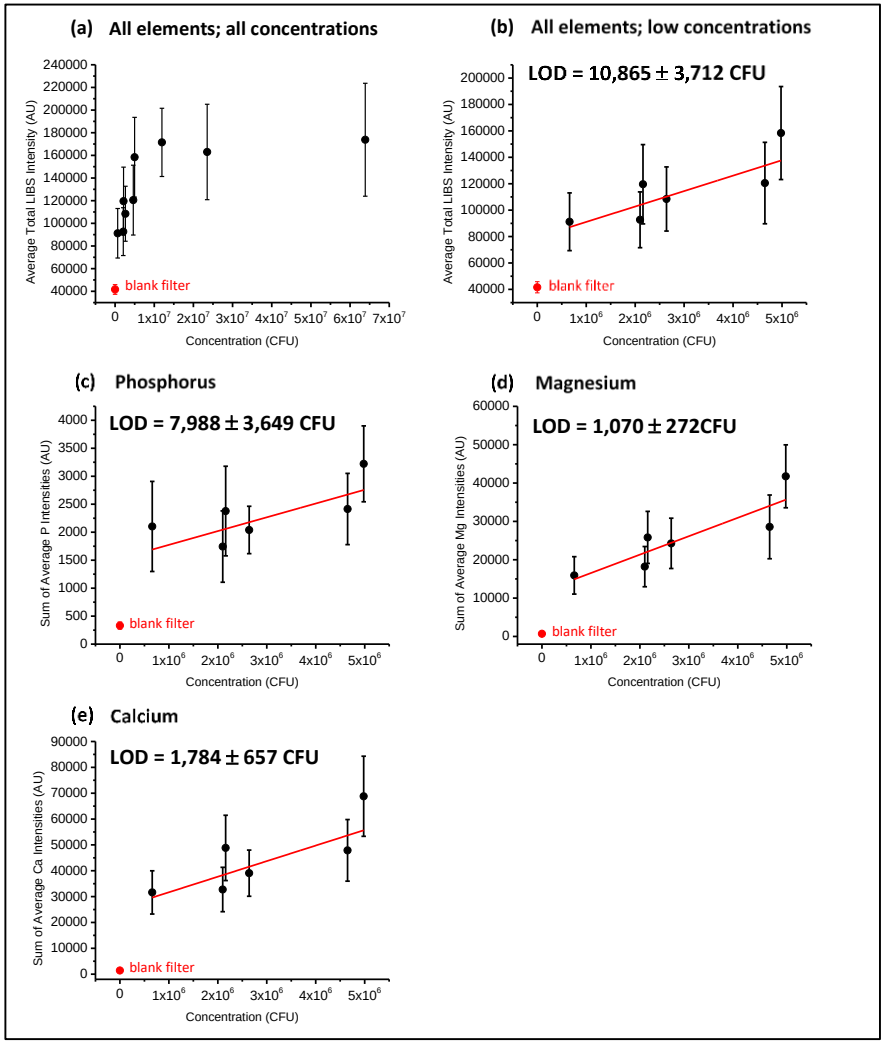
Cone vertex press fit into filter

Shooting Bacteria Concentrated With Cone





Limits of Detection



A calibration curves constructed from forty spectra obtained from each of nine different concentrations.

LIBS bacterial limit of detection of 10,865 ± 3,712 CFU per laser ablation event for bacteria deposited on filters using the metal cone.

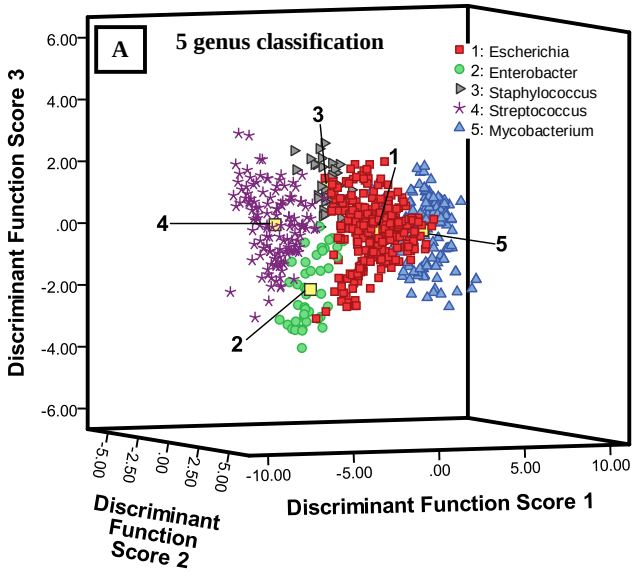
LOD's calculated using only certain elements observed in the LIBS spectra and present in very low concentrations in the filter were even lower:

1,070 ± 272CFU for magnesium
1,784 ± 657 CFU for calcium.

LOD on filter better, but number of cells required in fluid specimen is **WAY** lower!

When performed with no background

- ✓ We can identify a bacterial species, certainly its genus, with high sensitivity and specificity (confirmed by others).
- ✓ We can differentiate strains of *E. coli* (demonstrated by others in MRSA).
- ✓ Multiple multivariate techniques effective at discriminating spectra.



PLSDA

E. COLI	True	False
Positive	95.65%	9.17%
Negative	90.83%	4.35%

STAPHYLOCOCCUS	True	False
Positive	54.05%	0.51%
Negative	99.49%	45.95%

STREPTOCOCCUS	True	False
Positive	95.59%	1.02%
Negative	98.98%	4.41%

MYCOBACTERIUM	True	False
Positive	88.31%	1.06%
Negative	98.94%	11.69%

DFA

E. COLI	True	False
Positive	89.63%	15.95%
Negative	84.05%	10.37%

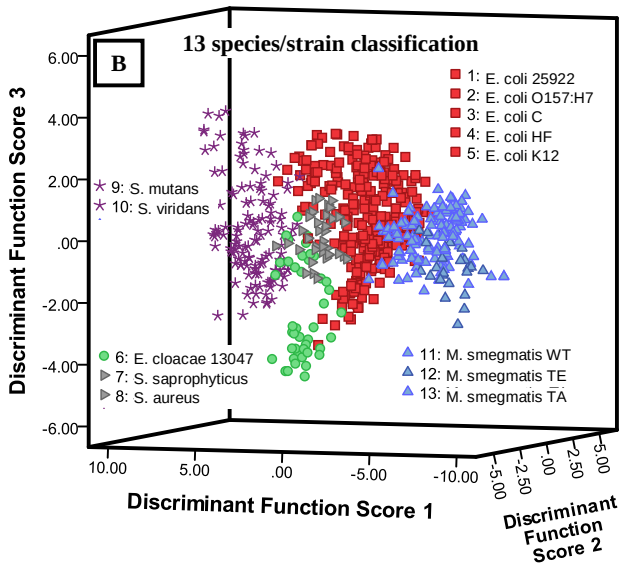
STAPHYLOCOCCUS	True	False
Positive	86.49%	5.85%
Negative	94.15%	13.51%

STREPTOCOCCUS	True	False
Positive	99.26%	13.32%
Negative	88.68%	0.74%

MYCOBACTERIUM	True	False
Positive	96.10%	4.08%
Negative	95.92%	3.90%

DFA: *Sensitivity*: 91.37 ± 16.39 % *Specificity*: 97.46 ± 9.35 %

PLSDA: *Sensitivity*: 93.13 ± 10.25 % *Specificity*: 90.60 ± 21.33 %



Results: We have already demonstrated…

- LIBS spectral fingerprint is a *sensitive* and *specific* (high rates of true positives, low rates of false positives) test to identify an unknown bacterial specimen or to differentiate between possible identifications
- This spectral fingerprint is *robust* and *reliable*, and exists through time (multiple tests spanning years on same strains of bacteria)
- In addition…

9 publications in Applied Physics Letters, Journal of Applied Physics, Applied Optics, Applied Spectroscopy, Spectrochimica Acta B, and others – confirmed by multiple other groups

Results: We have already demonstrated…

LIBS spectral fingerprint is:

- growth-medium independent
- independent of state of growth (how “old” the bacteria are)
- independent of whether the bacteria are live or dead (or inactivated by UV light)
- obtainable even when other types of bacteria or contaminants are present (mixed samples)
- obtainable from urine specimens
- capable of strain discrimination
- obtainable from about 500 bacteria

9 publications in Applied Physics Letters, Journal of Applied Physics, Applied Optics, Applied Spectroscopy, Spectrochimica Acta B, and others – confirmed by multiple other groups
